Coursera - Practical Machine Learning Project

Kelvin Leung 7/10/2018

Background

Using devices such as Jawbone Up, Nike FuelBand, and Fitbit it is now possible to collect a large amount of data about personal activity relatively inexpensively. These type of devices are part of the quantified self movement – a group of enthusiasts who take measurements about themselves regularly to improve their health, to find patterns in their behavior, or because they are tech geeks. One thing that people regularly do is quantify how much of a particular activity they do, but they rarely quantify how well they do it. In this project, your goal will be to use data from accelerometers on the belt, forearm, arm, and dumbell of 6 participants. They were asked to perform barbell lifts correctly and incorrectly in 5 different ways. More information is available from the website here: http://groupware.les.inf.puc-rio.br/har (see the section on the Weight Lifting Exercise Dataset).

Load libraries

```
library(caret)
## Loading required package: lattice
## Loading required package: ggplot2
library(rattle)
## Rattle: A free graphical interface for data science with R.
## Version 5.1.0 Copyright (c) 2006-2017 Togaware Pty Ltd.
## Type 'rattle()' to shake, rattle, and roll your data.
library(rpart)
library(rpart.plot)
library(RColorBrewer)
library(cvTools)
## Loading required package: robustbase
library(randomForest)
## randomForest 4.6-14
## Type rfNews() to see new features/changes/bug fixes.
##
## Attaching package: 'randomForest'
## The following object is masked from 'package:rattle':
##
##
       importance
## The following object is masked from 'package:ggplot2':
##

       margin
```

Data loading

```
train_data <- read.csv(url("https://d396qusza40orc.cloudfront.net/predmachlearn/pml-training.csv"), head
dim(train_data)

## [1] 19622    160

test_data <- read.csv(url("https://d396qusza40orc.cloudfront.net/predmachlearn/pml-testing.csv"), headed
dim(test_data)

## [1] 20 160</pre>
```

The training set has 19622 observations and each observation has 160 columns. We notice that many columns have N/A values or blank values. So we will remove them because they will not produce any information. Also, the first seven columns give information about the people who did the test and the timestamps. We will remove these columns in our model. Note, the "classe" variable is in the last column of our training set.

The testing set has 20 cases. It will be used to test the accuracy of our models.

Cleansing procedure

Here is the R code to remove the columns that has N/A or "" values.

```
# removing columns having value of "N/A" or "" value that have at least 90% of the total number of rows
tidx_2remove <- which(colSums(is.na(train_data) | train_data=='') > 0.9* dim(train_data)[1])
# removing those columns
train_clean <- train_data[ ,-tidx_2remove]</pre>
# removing the first 7 columns that are irrelevant to the prediction model
train_clean <- train_clean[ ,-(1:7)]</pre>
dim(train_clean)
## [1] 19622

```

From the above, the columns of "train_clean" match with the columns of "test_clean", except for the last column, "problem id". But we do not need to care about the "problem id" column at this time.

Build Classification models

We use "decision tree" and "random forest" to build classification models.

First, we partiion the training data into 2 parts and use cross validation method to validate the model we

build.

To ensure the reproductivity of this experiment, we initial the seed to 12345.

```
set.seed(12345)
dim(train_clean)

## [1] 19622 53

dim(test_clean)

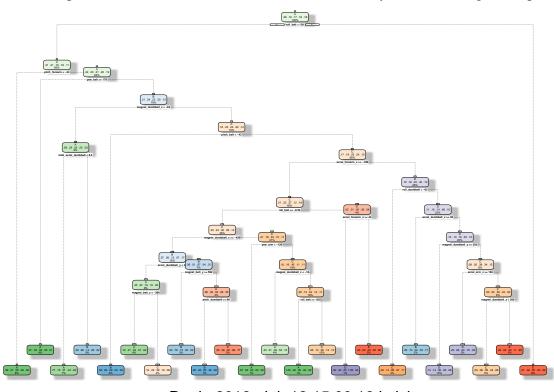

## [1] 20 53

tr1 <- createDataPartition(train_clean$classe, p=0.6, list=FALSE)
training <- train_clean[tr1,]
testing <- train_clean[-tr1,]

##Train with decision tree

mDT <- rpart(classe~., data=training, method='class')
fancyRpartPlot(mDT)</pre>
```

Warning: labs do not fit even at cex 0.15, there may be some overplotting

Rattle 2018-Jul-12 15:00:18 kelvin

##Confu-

sion matrix using out-of-sample data in the decision tree model

```
ctree_pred <- predict(mDT, newdata=testing, type='class')
cm_ctree <- confusionMatrix(ctree_pred, testing$classe)
cm_ctree</pre>
```

##
  Tuning parameter 'shrinkage' was held constant at a value of 0.1
##
## Tuning parameter 'n.minobsinnode' was held constant at a value of 10
## Accuracy was used to select the optimal model using the largest value.
## The final values used for the model were n.trees = 150,
    interaction.depth = 3, shrinkage = 0.1 and n.minobsinnode = 10.

I beleive that Random Forest model (n=100) and Stochastic Gradient Boosting (gbm) are very accurate in terms of the out-of-sample accuracy, i.e. 99.44% for Random Forest 96.39% for gbm and 72.67% for Decision Tree model respectively. We can reply on either Random Forest or Stochastic Gradient Boosting (gbm) for the prediction. One caution is that the time it took to build Random Forest is much faster than that for gbm. Therefore, we would decide to use Random Forest to get the perliminary prediction result as much as possible.
